HOMEWORK 1 - Problem 1

Yizhan Ao

Let $f(x) = e^x + x^2 - 5x$.

(a) The bracket $[1.5, 2]$ contains a root. Explain why using the Intermediate Value Theorem. For this bracket, estimate the number of iterations N that would be needed to compute the root to an accuracy of 10^{-4} .

```
clear all
syms f(x) x y
```

```
f(x) = exp(x) + x^2 - 5*x;
double(f(1.5))
```

```
ans =
    -0.7683
```

```
double(f(2))
```

```
ans =
    1.3891
```

```
%Since f(x) is continuous on [1.5, 2], and f(1.5) = -0.7683 < 0 and
f(2) = 1.3891 > 0.
%By the Intermediate Theorem, f(x) has at least one root on the
interval [1.5, 2].
```

(b) The bracket given in (a) contains a root, but there is another root. Find a bracket for it. Then use the bisection method to find the two roots to an accuracy of 10^{-4} .

```
A = double(f(0));
fprintf(['Because f(0)= %g > 0 f(1.5)= %g < 0. So find a root in', ...
' [0, 1.5]'], A ,double(f(1.5)))
```

```
Because f(0)= 1 > 0 f(1.5)= -0.768311 < 0. So find a root in [0, 1.5]
```

```
bisect(@(x) exp(x) + x^2 - 5*x, 0, 1, 0.0001)
```

```
ans =  
0.2805
```

```
bisect(@(x) exp(x) + x^2 - 5*x, 1.5, 2, 0.0001)
```

```
ans =  
1.7339
```

So roots are at $x = 0.2805$ and at $x = 1.7339$.

HOMEWORK 1 - Problem 2

Consider the cubic $f(x) = x^3 - x - 1$. (a) Use the MATLAB command `fzero` to find a root in the interval $[1, 2]$.

```
fzero(@(x) x^3 - x - 1, 1)
```

```
ans =  
1.3247
```

(b) Show that $f(x) = 0$ can be rewritten as a fixed point problem for both the functions (i) $g_1(x) = x^3 - 1$, and (ii) $g_2(x) = (1+x)^{1/3}$.

```
g1= x^3 - 1;  
g2=(1+x)^(1/3);  
g1' == diff(g1)  
g2' == diff(g2)  
%Let  $f(x) = x^3 - x - 1 = 0$ , then we can have  $x^3 - x - 1 = 0$  then  $x^3 - 1 = x$   
%So we can write  $g_1(x) = x^3 - 1$ .  
% $x^3 - x - 1 = 0$   
% $x^3 = 1 + x$   
% $x = (1 + x)^{1/3}$   
%Then  $g_2(x) = (1 + x)^{1/3}$ .
```

```
ans =  
conj(x)^3 - 1 == 3*x^2  
ans =  
conj((x + 1)^(1/3)) == 1/(3*(x + 1)^(2/3))
```

(c) Which of the functions g_1 and g_2 is a contraction mapping near the root r from part (a)? Which of g_1 or g_2 will be successful in making the iteration $x_{i+1} = g(x_i)$ converge locally to the root r ?

```
diff((1 + x)^(1/3))
```

```
ans =  
1/(3*(x + 1)^(2/3))
```

```
%Derivative of  $g_1$  and  $g_2$ ,  $g_1' = 3 * x^2$  and  $g_2' = 1/(3*(x + 1)^(2/3))$ .  
%Since  $g_1'(1) = 3$  and  $g_1'(2) = 12$  and  $g_1'$  is strictly increasing on  $[1, 2]$ . So  $g_1'$  diverges.  
% $g_2'$  is continuous and decreasing on  $[1, 2]$ ,  $g_2'(1) = 0.21$  and  $g_2'(2) = 0.1602$ 
```

%So # L, $0 \leq L < 1$ s.t $|g_2'(x)| \leq L < 1 \quad \forall x \in [1,2]$, g_2' converges.
 %Thus by the Contraction Mapping Theorem only g_2 is a contraction on $[1,2]$,
 % g_2 will be making the iteration $x_{i+1} = g(x_i)$ converge locally to the root r .

(d) Write a script or function in MATLAB to carry out 10 steps of the fixed point iteration for both g_1 and g_2 , each starting with the guess $x_0 = 0$. What approximate root does your algorithm give for g_1 ? For g_2 ? Are your results consistent with the analysis from part (c)?

This is the code from the fpi root function
`[root,tol] = fpi_root(g,x0,N) fprintf('fixed point method g(x)')
 disp(g) for count= 1:N xx =g(x0); x0=xx; rr(count) = xx; fprintf('\tAfter %d steps, root = %f\n', count, x0)
 end root = rr(count); tol=abs(g(root)) hold off`

```
g1 = @(x) x.^3 - 1;  
g2 = @(x) (1 + x).^(1/3);
```

```
disp('Fixed point iteration for g1 starts with x0=0:')  
fpi_root(g1,0,10)
```

Fixed point iteration for g1 starts with x0=0:

fixed point method g(x) @(x)x.^3-1

After 1 steps, root = -1.000000

After 2 steps, root = -2.000000

After 3 steps, root = -9.000000

After 4 steps, root = -730.000000

After 5 steps, root = -389017001.000000

After 6 steps, root = -58871587162270591457689600.000000

After 7 steps, root =

-204040901322752646989478259680513109526757826056202557355691431285390611316736.0

After 8 steps, root =

-84947714722373876912426115385994721993330450340708886432958705831500286122585831

After 9 steps, root = -Inf

After 10 steps, root = -Inf

tol =

Inf

ans =

-Inf

```
disp('Fixed point iteration for g2 starts with x0=0:')
fpi_root(g2,0,10)
```

```
Fixed point iteration for g2 starts with x0=0:
```

```
fixed point method g(x)      @(x)(1+x).^(1/3)
```

```
After 1 steps, root = 1.000000
```

```
After 2 steps, root = 1.259921
```

```
After 3 steps, root = 1.312294
```

```
After 4 steps, root = 1.322354
```

```
After 5 steps, root = 1.324269
```

```
After 6 steps, root = 1.324633
```

```
After 7 steps, root = 1.324702
```

```
After 8 steps, root = 1.324715
```

```
After 9 steps, root = 1.324717
```

```
After 10 steps, root = 1.324718
```

```
tol =
```

```
1.3247
```

```
ans =
```

```
1.3247
```

```
%Only g2 is successful in making the iteration xi+1 = g(xi) converge  
locally to the root r.
```

```
%The results consistent with the analysis from part (c).
```
